

PHYS 325: Lecture 1

Cliff Sun

August 27, 2024

Lecture Span

1. Course Overview
2. Newton's Laws

Course Overview

Logistics

- Lecture attendance via gradescope: answer > 50% of questions. (NOT GRADED ON CORRECTNESS)
- Bonus points: Must ask question during Office Hours (2pts per week up to 30pts or 3%)

Overview of Course Topics

1. Newtonian Dynamics
2. Conservation Laws
3. Damped & Driven Oscillations
4. Motion in rotating reference frames
5. Lagrangian Mechanics

Ch 1: Newton's Laws

1.1 General Concepts

1.1.1 Space/Position

Choosing a Reference Frame

Note: In general, it's important to choose a coordinate system and use linearly-independent, unit vectors that span all of your chosen vector space. Example includes:

$$\vec{i}, \vec{j}, \vec{k} \quad (1)$$

In this class, we will use mostly Cartesian Coordinates and thus Cartesian Basis Vectors as seen in eq (1). Later, we will use spherical & cylindrical coordinates to describe rotational motion.

Position Vector

We can choose a \vec{r} that goes from $0 \rightarrow \rho$. This position vector will be a linear combination of the basis vectors such as

$$\vec{r} = a\vec{e}_x + b\vec{e}_y + c\vec{e}_z \leftarrow \text{Basis vector notation} \quad (2)$$

Another form of notation of listing this vector is

$$\vec{r} = (a, b, c) \leftarrow \text{Vector notation} \quad (3)$$

Important thing to note: Physical Characteristics remain the same regardless of the chosen coordinate frames.

1.1.2 Time

Typically, Time is depicted with the variable t or T . In Classical Mechanics, time is **absolute** unlike Special Relativity. This means that time is measured equally by all observers.

Consequences

- Information travels at an infinite speed, i.e physical changes are noticed immediately
- People can communicate instantly

Thus, Newtonian Mechanics are valid for $v \ll c$ and $m \gg e$ where e = mass of electron and c = speed of light .

1.1.3 Mass

Mass is typically depicted using variables m, M and the units of mass is [kg]. This is an intrinsic property of an object. It characterizes the object's inertia; i.e resistance to acceleration.

1.1.4 Point/Particle

It is an object of mass m but neglected size.

Consequences

- Kinetic Energy is purely translational (no rotational kinetic energy)
- Size of object \ll distance to observer

1.1.5 Force

Force is depicted by the symbol \vec{F} , and is the cause of an object's motion.

Strategy for describing the motion of an object

- Identify all forces and their directions
- Use vector addition to find the net force

Recap on Vector Calculus

Consider two vectors $\vec{r} = (r_1, r_2, r_3)$ and $\vec{s} = (s_1, s_2, s_3)$.

Properties

- Addition or $\vec{r} + \vec{s}$
- Scalar Multiplication for some $a \in \mathbb{R}$
- Magnitude (norm), basically $r = \|\vec{r}\| \iff \sqrt{\vec{r} \cdot \vec{r}} \iff \sqrt{\sum_i (r_i^2)}$.
- Dot Product: $f : \mathbb{R}^n \rightarrow \mathbb{R}$. This operation commutes, such that $\vec{s} \cdot \vec{r} \iff \vec{r} \cdot \vec{s}$
- Cross product: $f : \mathbb{R}^3 \rightarrow \mathbb{R}^3$. Denoted as $\vec{r} \times \vec{s} = \vec{p}$. Such that $\vec{p} \cdot \vec{r} = \vec{p} \cdot \vec{s} = 0$. In other words, \vec{p} is orthogonal to both \vec{r} and \vec{s} .
